

Project 1
CS 628/628A: Computer System Security
2015-2016 -- Semester II
Computer Science and Engineering Department
Indian Institute of Technology Kanpur
Due Date: First 3 exercises by Jan 28, 2017 11:55 pm
Final 3 exercises by Feb 4, 2017, 11:55 pm
Acknowledgement: This project is based on a homework used at MIT for
MIT-6.858 course in 2014

1. Introduction

You will do a sequence of projects in this course. These sequence of projects will give you practical experience with common attacks and counter measures. To make the issues concrete, you will explore the attacks and counter measures in the context of the **zoobar** web application in some of the subsequent projects. Following is a list of possible projects that might be assigned to you. *Not all of these projects will be assigned, as there are other projects related to other topics in the class.* But just to give you an idea of possible subsequent projects -- here is a possible list of projects. (**Since multiple projects will depend on your current project, you are strongly urged to do this project seriously and completely.**)

Project 1: you will explore the base structure of the **zoobar** web application, and use buffer overrun attacks to break its security properties.

Project 2: you will improve zoobar web application by using privilege separation, so that if one components is compromised, the adversary doesn't have control over the whole web application.

Project 3: you will build a program analysis tool (likely based on symbolic execution) to find bugs in Python code such as the zoobar web application.

Project 4: you will perform a security audit of two other student's solutions. You probably want to do a good job in project 2 and project 3.

Project 5: you will improve the zoobar application against browser attacks.

Project 6: you will extend the zoobar application to support javascript user profiles in a secure manner.

Project 1 will introduce you to *buffer overflow* vulnerabilities, in the context of a web server called **zookws**. The **zookws** web server is running a simple python web application, **zoobar**, where users transfer "zoobars" (credits) between each other. You will find buffer overflows in the **zookws** web server code, write exploits for the buffer overflows to inject code into the server, figure out how to bypass non-executable stack protection, and finally look for other potential problems in the web server implementation. Later projects look at other security aspects of the **zoobar** and **zookws** infrastructure.

Each project may require you to learn a new programming language or some other piece of infrastructure. For example, in this project you must become intimate familiar with certain aspects of the **C language**, **x86 assembly language**, **gdb**, etc. The projects do so because that allows you to understand attacks and defenses in realistic situations. Often you need to understand certain parts of this new infrastructure in detail; security weaknesses often show up in corner cases, and so you need to understand the details to craft exploits and design defenses for those corner cases. These two factors (new infrastructure and details) can make the projects time consuming. **You should start early on the projects and work on them daily for some limited time** (each project has several exercises), **instead of trying to do all exercises in a single shot before the deadline**. You should also try to understand the necessary details, instead of muddling your way through the exercises. If you don't, the projects will take a lot of time. If you get stuck on a detail, post a question on CS628 google group or see the TAs.

Several projects, including this project, ask you to design exploits. These exploits are realistic enough that you might be able to use them for a real attack, but you should **not** do so. The point of the designing exploits is to teach you how to defend against them, not how to use them---attacking computer systems is illegal and can get you into serious trouble. **Please Don't do it.**

2. Project infrastructure

Exploiting buffer overflows requires precise control over the execution environment. A small change in the compiler, environment variables, or the way the program is executed can result in slightly different memory

layout and code structure, thus requiring a different exploit. For this reason, this project uses a VirtualBox virtual machine to run the vulnerable web server code.

Once you have VirtualBox installed on your machine, you should download the course VM image, provided with this project assignment and unpack it on your computer. This virtual machine contains an installation of Ubuntu 14.04.1 Linux, and the following accounts have been created inside the VM. The name of the VM is vm-CS628. The file containing the VM is provided along with this document via <http://security.cse.iitk.ac.in>

Username	Password	Description
root	CS628A	You can use the root account to install new software packages into the VM, if you find something missing, using apt-get install pkgname .
httpd	CyberSecurity	The httpd account is used to execute the web server, and contains the source code you will need for this project assignment, in /home/httpd/lab .

You can either log into the virtual machine using its console, or you can use ssh to log into the virtual machine over the (virtual) network. To determine the virtual machine's IP address, log in as root on the console and run **/sbin/ifconfig eth0** and find the iNET address. For the rest of the document we assume this IP address is 192.168.134.128 for example. Each of you will get a different IP address of course.

The files you will need for this project assignment is already preloaded in the VM as **~httpd/lab**

```
httpd@vm-628:~$ cd lab
httpd@vm-628:~/lab$
```

proceed with this project assignment, make sure you can compile the zookws web server:

```
httpd@vm-628:~/lab$ make
```

```
zookld.c -c -o zookld.o -m32 -g -std=c99 -Wall
-Werror -D_GNU_SOURCE -fno-stack-protector
```

```
http.c -c -o http.o -m32 -g -std=c99 -Wall -Werror
-D_GNU_SOURCE -fno-stack-protector
```

```
zookld.o http.o -lcrypto -o zookld
```

```
zookfs.c -c -o zookfs.o -m32 -g -std=c99 -Wall
-Werror -D_GNU_SOURCE -fno-stack-protector
```

```
zookfs.o http.o -lcrypto -o zookfs
```

```
zookfs zookfs-nxstack
```

```
zookd.c -c -o zookd.o -m32 -g -std=c99 -Wall
-Werror -D_GNU_SOURCE -fno-stack-protector
```

```
zookd.o http.o -lcrypto -o zookd
```

```
zookd-nxstack
```

```
zookfs zookfs-exstack
```

```
execstack -s zookfs-exstack
```

```
zookd-exstack
```

```
execstack -s zookd-exstack
```

```
zookfs.c -c -o zookfs-withssp.o -m32 -g -std=c99
-Wall -Werror -D_GNU_SOURCE
```

```
http.c -c -o http-withssp.o -m32 -g -std=c99 -Wall
-Werror -D_GNU_SOURCE
```

```

zookfs-withssp.o http-withssp.o -lcrypto -o
zookfs-withssp

-std=c99 -Wall -Werror -D_GNU_SOURCE -fno-
stack-protector
run-shellcode.o -lcrypto -o run-shellcode
shellcode.o

```

```
httpd@vm-628:~/lab$
```

The server consists of the following components.

zookld, a launcher daemon that launches services configured in the file **zook.conf**.

zookd, a dispatcher that routes HTTP requests to corresponding services.

zookfs and other services that may serve static files or execute dynamic scripts.

After **zookld** launches configured services, **zookd** listens on a port (**8080** by default) for incoming HTTP requests and reads the first line of each request for dispatching. In this project, **zookd** is configured to dispatch every request to the **zookfs** service, which reads the rest of

the request and generates a response from the requested file. Most HTTP-related code is in `http.c`. [Here](#) is a tutorial of the HTTP protocol.

There are two versions of the web server you will be using:

`zookld`, `zookd-exstack`, `zookfs-exstack`, as configured in the file `zook-exstack.conf`;

`zookld`, `zookd-nxstack`, `zookfs-nxstack`, as configured in the file `zook-nxstack.conf`.

In the first one, the `*-exstack` binaries have an executable stack, which makes it easier to inject executable code given a stack buffer overflow vulnerability. The `*-nxstack` binaries in the second version have a non-executable stack, and you will write exploits that bypass non-executable stacks later in this project assignment.

In order to run the web server in a predictable fashion---so that its stack and memory layout is the same every time---you will use the `clean-env.sh` script. This is the same way in which we will run the web server during grading, so make sure all of your exploits work on this configuration!

The reference binaries of `zookws` are provided in `bin.tar.gz`, which we will use for grading. Make sure your exploits work on those binaries.

Now, make sure you can run the `zookws` web server and access the `zoober` web application from a browser running on your machine, as follows:

```
httpd@vm-628:~/lab$ /sbin/ifconfig eth0
eth0          Link encap:Ethernet  HWaddr
00:0c:29:57:90:a1
```

```

inet   addr: 198.168.134.128
Bcast:198.168.134.255
Mask:255.255.255.0
inet6  addr: fe80::20c:29ff:fe57:90a1/64
Scope:Link
UP BROADCAST RUNNING MULTICAST  MTU:1500
Metric:1
RX packets:149 errors:0  dropped:0
overruns:0  frame:0
TX  packets:94 errors:0  dropped:0
overruns:0  carrier:0
collisions:0  txqueuelen:1000
RX bytes:15235 (15.2  KB)  TX  bytes:12801
(12.8  KB)
Interrupt:19  Base address:0x2000

```

```

httpd@vm-628:~/lab$ ./clean-env.sh  ./zookld  zook-
exstack.conf

```

The **/sbin/ifconfig** command will give you the virtual machine's IP address. In this particular example you should go to **<http://198.168.134.128:8080/>** from a browser on your host machine.

If something doesn't seem to be working, try to figure out what went wrong, or contact the course TAs or the instructor before proceeding further.

Part 1: Finding buffer overflows

In the first part of this project assignment, you will find buffer overflows in the provided web server. Read Aleph One's article, "[Smashing the Stack for Fun and Profit](#)", as well as paper posted associated with this project assignment titled "**Buffer Overflows: Attacks and Defenses for the Vulnerability of the Decade**", to figure out how buffer overflows work.

Exercise 1. Study the web server's code, and find examples of code vulnerable to memory corruption through a buffer overflow. Write down a description of each vulnerability in the file `/home/httpd/project/bugs.txt`; use the format described in that file. For each vulnerability, describe the buffer which may overflow, how you would structure the input to the web server (i.e., the HTTP request) to overflow the buffer, and whether the vulnerability can be prevented using stack canaries. Locate at least 5 different vulnerabilities.

You can use the command **`make check-bugs`** to check if your `bugs.txt` file matches the required format, although the command will not check whether the bugs you listed are actual bugs or whether your analysis of them is correct.

Now, you will start developing exploits to take advantage of the buffer overflows you have found above. We have provided template Python code for an exploit in `/home/httpd/project/exploit-template.py`, which issues an HTTP request. The exploit template takes two arguments, the server name and port number, so you might run it as follows to issue a request to `zookws` running on `localhost`:

```
httpd@vm-628:~/lab$ ./clean-env.sh ./zookld
zook-exstack.conf &
[1] 2676
httpd@vm-628:~/lab$ ./exploit-template.py
localhost 8080
HTTP request:
GET / HTTP/1.0
```

- - -

```
httpd@vm-628:~/lab$
```

You are free to use this template, or write your own exploit code from scratch. Note, however, that if you choose to write your own exploit, the exploit must run correctly inside the provided virtual machine. You will find **gdb** useful in building your exploits. As `zookws` forks off many processes, it can be difficult to debug the correct one. The easiest way to do this is to run the web server ahead of time with `clean-env.sh` and then attaching `gdb` to an already-running process with the `-p` flag. To help find the right process for debugging, `zookld` prints out the process IDs of the child processes that it spawns. You can also find the PID of a process by using `pgrep`; for example, to attach to `zookd-exstack`, start the server and, in another shell, run

```
httpd@vm-628:~/lab$ gdb -p $(pgrep zookd-
exstack)
--
0x4001d422 in _kernel_vsyscall ()
(gdb) break your-breakpoint
Breakpoint 1 at 0x1234567: file zookd.c, line
999.
(gdb) continue
Continuing.
```

Keep in mind that a process being debugged by `gdb` will not get killed even if you terminate the parent `zookld` process using `^C`. If you are having trouble restarting the web server, check for leftover processes from the previous run, or be sure to exit `gdb` before restarting `zookld`.

When a process being debugged by `gdb` forks, by default `gdb` continues to debug the parent process and does not attach to the child. Since `zookfs` forks a child process to service each request, you may find it helpful to have `gdb` attach to the child on fork, using the command `set follow-fork-mode child`. We have added that command to `/home/httpd/lab/.gdbinit`, which will take effect if you start `gdb` in that directory.

For this and subsequent exercises, you may need to encode your attack payload in different ways, depending on which vulnerability you are

exploiting. In some cases, you may need to make sure that your attack payload is URL-encoded; that is, use + instead of space and %2b instead of +. Here is a [URL encoding reference](#) and a handy [conversion tool](#). You can also use quoting functions in the python `urllib` module to URL encode strings. In other cases, you may need to include binary values into your payload. The Python [struct](#) module can help you do that. For example, `struct.pack("<I", x)` will produce a 4-byte (32-bit) binary encoding of the integer `x`.

Exercise 2. Pick two buffer overflows out of what you have found for later exercises (although you can change your mind later, if you find your choices are particularly difficult to exploit). The first *must* overwrite a return address on the stack, and the second *must* overwrite some other data structure that you will use to take over the control flow of the program.

Write exploits that trigger them. You do not need to inject code or do anything other than corrupt memory past the end of the buffer, at this point. Verify that your exploit actually corrupts memory, by either checking the last few lines of `dmesg | tail`, using `gdb`, or observing that the web server crashes.

Provide the code for the exploits in files called `exploit-2a.py` and `exploit-2b.py`, and indicate in `answers.txt` which buffer overflow each exploit triggers. If you believe some of the vulnerabilities you have identified in Exercise 1 cannot be exploited, choose a different vulnerability.

You can check whether your exploits crash the server as follows:

```
httpd@vm-628:~/lab$ make check-crash
```

Part 2: Code injection

In this part, you will use your buffer overflow exploits to inject code into the web server. The goal of the injected code will be to unlink (remove) a sensitive file on the server, namely `/home/httpd/grades.txt`.

Use the `*-exstack` binaries, since they have an executable stack that makes it easier to inject code. The `zookws` web server should be started as follows.

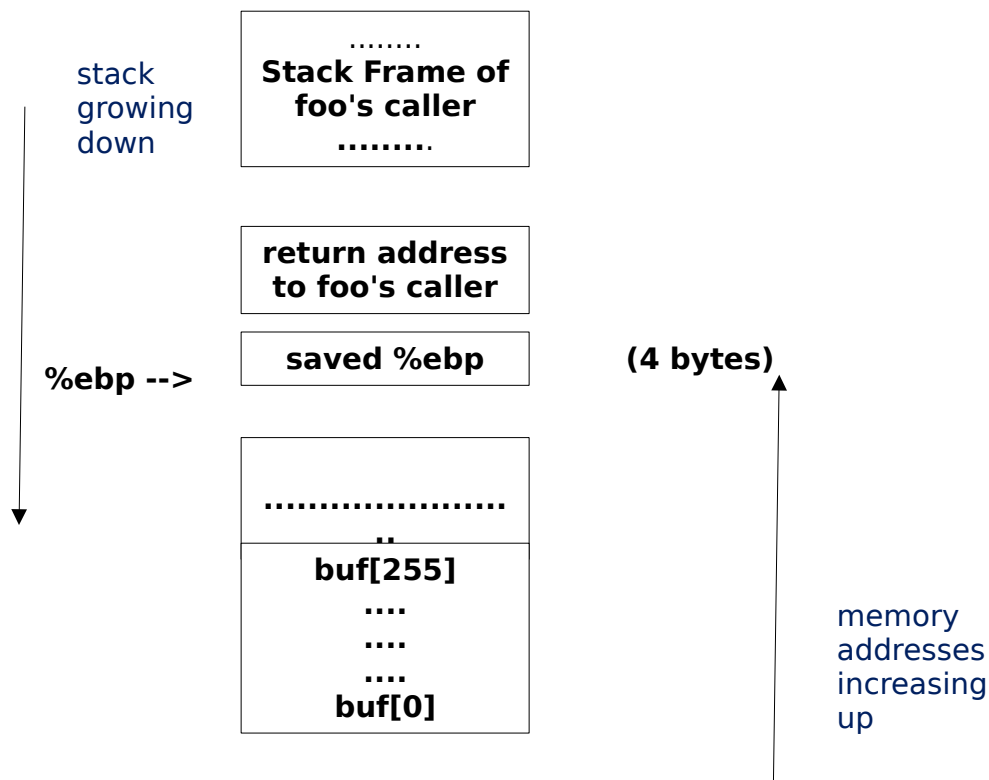

```
httpd@vm-628:~/lab$ ./clean-env.sh ./zookld  
zook-exstack.conf
```

We have provided Aleph One's shell code for you to use in `/home/httpd/lab/shellcode.S`, along with `Makefile` rules that produce `/home/httpd/lab/shellcode.bin`, a compiled version of the shell code, when you run `make`. Aleph One's exploit is intended to exploit `setuid-root` binaries, and thus it runs a shell. You will need to modify this shell code to instead unlink `/home/httpd/grades.txt`.

To help you develop your shell code for this next exercise, we have provided a program called `runshellcode` that will run your binary shell code, as if you correctly jumped to its starting point. For example, running it on Aleph One's shell code will cause the program to `execve("/bin/sh")`, thereby giving you another shell prompt:

```
httpd@vm-628:~/lab$ ./run-shellcode  
shellcode.bin  
$
```

When developing an exploit, you will have to think about what values are on the stack, so that you can modify them accordingly. For your reference, below you will find what the stack frame of some function `foo` looks like; here, `foo` has a local variable `char buf[256]`:

Note that the stack grows *down* in this figure, and memory addresses are increasing *up*.

When you're constructing an exploit, you will often need to know the addresses of specific stack locations, or specific functions, in a particular program. The easiest way to do this is to use `gdb`. For example, suppose you want to know the stack address of the `pn[]` array in the `http_serve` function in `zookfs-exstack`, and the address of its saved `%ebp` register on the stack. You can obtain them using `gdb` as follows:

```
httpd@vm-6858:~/lab$ gdb -p $(pgrep zookfs-exstack)
```

```
---
```

```
0x40022416 in _kernel_vsyscall ()
```

```
(gdb) break http_serve
```

```
Breakpoint 1 at 0x8049415: file http.c, line 248.
```

```
(gdb) continue
```

```
Continuing.
```

Be sure to run `gdb` from the `~/lab` directory, so that it picks up the `set follow-fork-mode child` command from `~/lab/.gdbinit`. Now you can issue an HTTP request to the web server, so that it triggers the breakpoint, and so that you can examine the stack of `http_serve`:

```
[New
proce
ss
1339]
[Swit
ching
to
proce
ss
1339
]
```

Breakpoint 1, `http_serve` (fd=3, name=0x8051014
"/") at `http.c:248`

```
248      void (*handler)(int, const char *) =
http_serve_none;
```

```
(gdb) print &pn
```

```
$1 = (char (*)[1024]) 0xbfffd10c
```

```
(gdb) info registers
```

```
eax          0x3    3
ecx          0x400bdec0 1074519744
edx          0x6c6d74 7105908
ebx          0x804a38e 134521742
esp          0xbfffd0a0 0xbfffd0a0
ebp          0xbfffd518 0xbfffd518
esi          0x0    0
edi          0x0    0
eip          0x8049415 0x8049415
<http_serve+9>
eflags      0x200286 [ PF SF IF ID ]
cs          0x73 115
ss          0x7b 123
ds          0x7b 123
```

```

es          0x7b 123
fs          0x0  0
gs          0x33 51
(gdb)

```

From this, you can tell that, at least for this invocation of `http_serve`, the `pn[]` buffer on the stack lives at address `0xbfffd10c`, and the value of `%ebp` (which points at the saved `%ebp` on the stack) is `0xbfffd518`.

Now it's your turn to develop an exploit.

Exercise 3. Starting from one of your exploits from Exercise 2, construct an exploit that hijacks control flow of the web server and unlinks `/home/httpd/grades.txt`. Save this exploit in a file called `exploit-3.py`.

Explain in `answers.txt` whether or not the other buffer overflow vulnerabilities you found in Exercise 1 can be exploited in this manner.

Verify that your exploit works; you will need to re-create `/home/httpd/grades.txt` after each successful exploit run.

Suggestion: first focus on obtaining control of the program counter. Sketch out the stack layout that you expect the program to have at the point when you overflow the buffer, and use `gdb` to verify that your overflow data ends up where you expect it to. Step through the execution of the function to the return instruction to make sure you can control what address the program returns to. The `next`, `stepi`, `info reg`, and `disassemble` commands in `gdb` should prove helpful.

Once you can reliably hijack the control flow of the program, find a suitable address that will contain the code you want to execute, and focus on placing the correct code at that address---e.g. a derivative of Aleph One's shell code.

Note: `SYS_unlink`, the number of the `unlink` syscall, is 10 or `'\n'` (newline). Why does this complicate matters? How can you get around it?

You can check whether your exploit works as follows:

```
httpd@vm-628:~/lab$ make check-exstack
```

The test either prints "PASS" or fails. We will grade your exploits in this way. If you use another name for the exploit script, change Makefile accordingly.

The standard C compiler used on Linux, gcc, implements a version of stack canaries (called SSP). You can explore whether GCC's version of stack canaries would or would not prevent a given vulnerability by using the SSP-enabled versions of the web server binaries (`zookd-withssp` and `zookfs-withssp`), by using the `zook-withssp.conf` config file when starting `zookld`.

Run `make prepare-submit-a`. The resulting `lab1a-handin.tar.gz` file will be graded. Submit it via mookit

Part 3: Return-to-libc attacks

Many modern operating systems mark the stack non-executable in an attempt to make it more difficult to exploit buffer overflows. In this part, you will explore how this protection mechanism can be circumvented. Run the web server configured with binaries that have a non-executable stack, as follows.

```
httpd@vm-628:~/project$ ./clean-env.sh  
./zookld zook-nxstack.conf
```

The key observation to exploiting buffer overflows with a non-executable stack is that you still control the program counter, after a RET instruction jumps to an address that you placed on the stack. Even though you cannot jump to the address of the overflowed buffer (it will not be executable), there's usually enough code in the vulnerable server's address space to perform the operation you want. Thus, to bypass a non-executable stack, you need to first find the code you want to execute. This is often a function in the standard library, called `libc`, such as `execl`, `system`, or `unlink`. Then, you need to arrange for the stack to look like a call to that function with the desired arguments, such as `system("/bin/sh")`. Finally, you need to arrange for the RET instruction to jump to the function you found in the first step. This attack is often called a *return-to-libc* attack. **The document 'return to**

libc" provided with this project assignment, contains a more detailed description of this style of attack

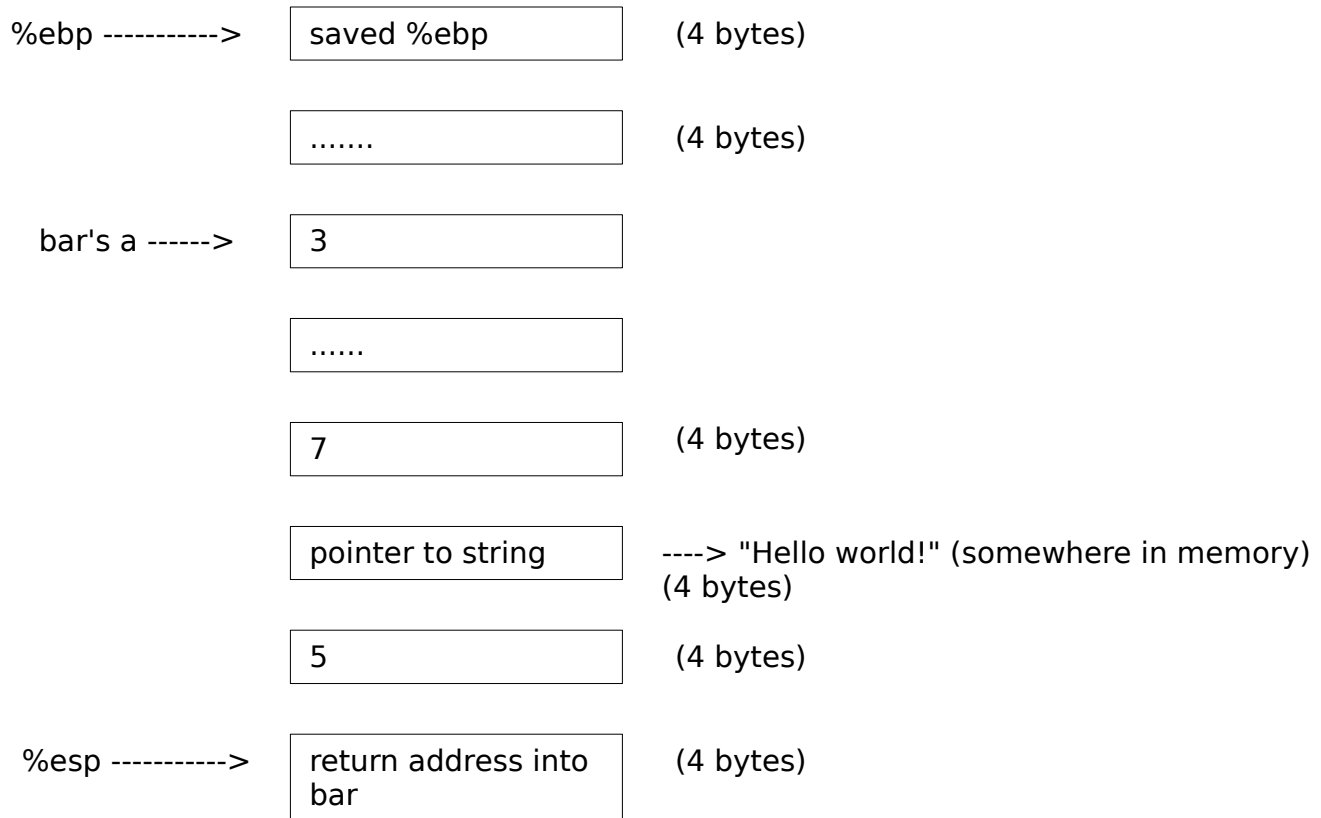

In the next exercise, you will need to understand the calling convention for C functions. For your reference, consider the following simple C program:

```
void
foo(int x, char *msg, int y)
{

    /* ... */
}

void bar (void) {
    int a = 3;
    foo(5, "Hello, world!", 7);
}
```

The stack layout when `bar` invokes `foo`, just after the program counter has switched to the beginning of `foo`, looks like this:

When `foo` starts running, the first thing it will do is save the `%ebp` register on the stack, and set the `%ebp` register to point at this saved value on the stack, so the stack frame will look like the one shown just above exercise 3.

Exercise 4. Starting from your two exploits in Exercise 2, construct two exploits that take advantage of those vulnerabilities to unlink `/home/httpd/grades.txt` when run on the binaries that have a non-executable stack. Name these new exploits `exploit-4a.py` and `exploit-4b.py`.

Although in principle you could use shellcode that's not located on the stack, for this exercise you should not inject any shellcode into the vulnerable process. You should use a return-to-libc (or at least a call-to-libc) attack where you vector control flow directly into code that existed before your attack.

In `answers.txt`, explain whether or not the other buffer overflow vulnerabilities you found in Exercise 1 can be exploited in this same manner.

You can test your exploits as follows:

```
httpd@vm-6858:~/lab$ make check-libc
```

The test either prints two "PASS" messages or fails. We will grade your exploits in this way. If you use other names for the exploit scripts, change Makefile accordingly.

Part 4: Fixing buffer overflows and other bugs

Now that you have figured out how to exploit buffer overflows, you will try to find other kinds of vulnerabilities in the same code. As with many real-world applications, the "security" of our web server is not well-defined. Thus, you will need to use your imagination to think of a plausible threat model and policy for the web server.

Exercise 5. Look through the source code and try to find more vulnerabilities that can allow an attacker to compromise the security of the web server. Describe the attacks you have found in `answers.txt`, along with an explanation of the limitations of the attack, what an attacker can accomplish, why it works, and how you might go about fixing or preventing it. You should ignore bugs in `zooobar`'s code. They will be addressed in future labs.

One approach for finding vulnerabilities is to trace the flow of inputs controlled by the attacker through the server code. At each point that the attacker's input is used, consider all the possible values the attacker might have provided at that point, and what the attacker can achieve in that manner.

You should find at least two vulnerabilities for this exercise.

Finally, you will explore fixing some of the vulnerabilities you have found in this project assignment.

Exercise 6. For each buffer overflow vulnerability you have found in Exercise 1, fix the web server's code to prevent the vulnerability in the first place. *Do not rely on compile-time or*

*runtime mechanisms such as stack canaries, removing **-fno-stack-protector**, baggy bounds checking, etc.*

Run **make prepare-submit**. The resulting **lab1-handin.tar.gz** file will be graded. So submit it via mookit.
